# 1 Installing the NetCDF Binaries

The easiest way to get netCDF is through a package management program, such as rpm, yum, adept, and others. NetCDF is available from many different repositories, including the default Red Hat and Ubuntu repositories.

Another way to get netCDF is to get a pre-built binary distribution. To get them, see <http://www.unidata.ucar.edu/downloads/netcdf/index.jsp>.

To install the binary distribution, uncompress and unpack the tar file. You will end up with 4 subdirectories, lib, include, man, and bin.

The lib subdirectory holds the netCDF libraries (C, Fortran, and C++). The include directory holds the necessary netcdf.h file (for C), netcdf.inc (for Fortran), netcdfcpp.h (for C++), and the .mod files (for Fortran 90). The bin directory holds the ngen and ncdump utilities, and the man directory holds the netCDF documentation.

You can have these directories anywhere you like, and use netCDF. But when compiling a netCDF program, you will have to tell the linker where to find the library (e.g. with the -L option of most C compilers), and you will also have to tell the C pre-processor where to find the include file (e.g. with the -I option).

If you are using shared libraries, you will also have to specify the library location for run-time dynamic linking. See your compiler documentation. For some general information see the netCDF FAQ “How do I use shared libraries” at [http://www.unidata.ucar.edu/netcdf/faq.html#using\\_shared](http://www.unidata.ucar.edu/netcdf/faq.html#using_shared).

## 2 Quick Instructions for Installing NetCDF on Unix

Who has time to read long installation manuals these days?

When building netCDF-4, you must first decide whether to support the use of HDF5 as a storage format.

### 2.1 Building NetCDF Without HDF5

If you don't want netCDF-4/HDF5, then build like this:

```
./configure --prefix=/home/ed/local --disable-netcdf-4
make check install
```

(Replace “/home/ed/local” with the name of the directory where netCDF is to be installed.)

If you get the message that netCDF installed correctly, then you are done!

### 2.2 Building NetCDF With HDF5

If you want to use the HDF5 storage format, you must have the HDF5 1.8.6 release. You must also have the zlib compression library, version 1.2.5. Both of these packages are available from the netCDF-4 ftp site at <ftp://ftp.unidata.ucar.edu/pub/netcdf/netcdf-4>.

Make sure you run “make check” for the HDF5 and zlib distributions. They are very well-behaved distributions, but sometimes the build doesn't work (perhaps because of something subtly misconfigured on the target machine). If one of these libraries is not working, netCDF will have serious problems.

Optionally, you can also build netCDF-4 with the szip 2.0 library (a.k.a. szlib). NetCDF cannot create szipped data files, but can read HDF5 data files that have used szip.

There are license restrictions on the use of szip, see the HDF5 web page: [http://hdf.ncsa.uiuc.edu/doc\\_resource/SZIP/Commercial\\_szip.html](http://hdf.ncsa.uiuc.edu/doc_resource/SZIP/Commercial_szip.html). These license restrictions seem to apply to commercial users who are writing data. (Data readers are not restricted.) But here at NetCDF World Headquarters, in Sunny Boulder, Colorado, there are no lawyers, only programmers, so please read the szip documents for the license agreement to see how it applies to your situation.

If you wish to use szip, get it from the HDF5 download page: <http://hdfgroup.org/HDF5//HDF5/release/>

If “make check” fails for either zlib or HDF5, the problem must be resolved before the netCDF-4 installation can continue. For HDF5 problems, send email to the HDF5 help desk: [help@hdfgroup.org](mailto:help@hdfgroup.org).

Build zlib like this:

```
./configure --prefix=/home/ed/local
make check install
```

Then you build HDF5, specifying the location of the zlib library:

```
./configure --with-zlib=/home/ed/local --prefix=/home/ed/local
make check install
```

Note that for shared libraries, you may need to add the install directory to the LD\_LIBRARY\_PATH environment variable. See the FAQ for more details on using shared libraries: <http://www.unidata.ucar.edu/netcdf/faq.html>.

If you are building HDF5 with `szip`, then include the `-with-szlib=` option, with the directory holding the `szip` library.

After HDF5 is done, build `netcdf`, specifying the location of the HDF5, `zlib`, and (if built into HDF5) the `szip` header files and libraries in the `CPPFLAGS` and `LDFLAGS` environment variables.

```
CPPFLAGS=-I/home/ed/local/include LDFLAGS=-L/home/ed/local/lib ./configure --prefix=/h
make check install
```

The `configure` script will try to find necessary tools in your path. When you run `configure` you may optionally use the `-prefix` argument to change the default installation directory. The above examples install the `zlib`, HDF5, and `netCDF-4` libraries in `/home/ed/local/lib`, the header file in `/home/ed/local/include`, and the utilities in `/home/ed/local/bin`.

The default install root is `/usr/local` (so there's no need to use the `prefix` argument if you want the software installed there).

If HDF5 and `zlib` are found on your system, they will be used by `netCDF` in the build. To prevent this use the `-disable-netcdf-4` argument to `configure`.

For static build, to use `netCDF-4` you must link to all the libraries, `netCDF`, HDF5, `zlib`, and (if used with HDF5 build) `szip`. This will mean `-L` options to your build for the locations of the libraries, and `-l` (lower-case L) for the names of the libraries.

For example, one user reports that she can build other applications with `netCDF-4` by setting the `LIBS` environment variable:

```
LIBS='-L/X/netcdf-4.0/lib -lnetcdf -L/X/hdf5-1.8.6/lib -lhdf5_hl -lhdf5 -lz -lm -L/X/s
```

For shared builds, only `-lnetcdf` is needed. All other libraries will be found automatically.

The `nc-config` command can be used to learn what options are needed for the local `netCDF` installation.

## 2.3 Building with HDF4 Support

The `netCDF-4` library can (since version 4.1) read HDF4 data files, if they were created with the SD (Scientific Data) API. To enable this feature, use the `-enable-hdf4` option. The location for the HDF4 header files and library must be set in the `CPPFLAGS` and `LDFLAGS` options.

## 3 Building and Installing NetCDF on Unix Systems

The latest version of this document is available at <http://www.unidata.ucar.edu/netcdf/docs/netcdf-inst>

This document contains instructions for building and installing the netCDF package from source on various platforms. Prebuilt binary releases are (or soon will be) available for various platforms from <http://www.unidata.ucar.edu/downloads/netcdf/index.jsp>.

A good general tutorial on how software is built from source on Linux platforms can be found at <http://www.tuxfiles.org/linuxhelp/softinstall.html>.

### 3.1 Installation Requirements

If you wish to build from source on a Windows (Win32) platform, different instructions apply. See [Chapter 5 \[Building on Windows\]](#), page 21.

Depending on the platform, you may need up to 25 Mbytes of free space to unpack, build, and run the tests. You will also need a Standard C compiler. If you have compilers for FORTRAN 77, FORTRAN 90, or C++, the corresponding netCDF language interfaces may also be built and tested. Compilers and associated tools will only be found if they are in your path, or if you specify the path and compiler in the appropriate environment variable. (Example for csh: `setenv CC /some/directory/cc`).

If you want to run the large file tests, you will need about 13 GB of free disk space, as some very large files are created. The created files are immediately deleted after the tests complete. These large file tests are not run unless the `-enable-large-file-tests` option is used with `configure`. (The `-with-temp-large` option may also be used to specify a directory to create the large files in).

Unlike the output from other netCDF test programs, each large test program deletes its output before successfully exiting.

To use the netCDF-4 features you will also need to have a HDF5-1.8.6 release installed. HDF5, in turn, must have been built with `zlib`, version 1.2.5.

A tested version of HDF5 and `zlib` can be found at the netCDF-4 ftp site at <ftp://ftp.unidata.ucar.edu/pub/netcdf/netcdf-4>.

For more information about HDF5 see the HDF5 web site at <http://hdfgroup.org/HDF5/>. For more information about `zlib` see the `zlib` web site at <http://www.zlib.net>.

To use the DAP features you will also need to have a version of `libcurl` (version 7.18.0 or later) installed. Depending on how this library was built, you may also need `zlib` (version 1.2.5 or later). Information about `libcurl` may be obtained at <http://curl.haxx.se>.

### 3.2 Specifying the Environment for Building

The netCDF `configure` script searches your path to find the compilers and tools it needed. To use compilers that can't be found in your path, set their environment variables.

The `configure` script will use `gcc` and associated GNU tools if they are found. Many users, especially those with performance concerns, will wish to use a vendor supplied compiler.

For example, on an AIX system, users may wish to use `xlc` (the AIX compiler) in one of its many flavors. Set environment variables before the build to achieve this.

For example, to change the C compiler, set `CC` to `xlC` (in sh: `export CC=xlC`). (But don't forget to also set `CXX` to `xlC`, or else configure will try to use `g++`, the GNU C++ compiler to build the netCDF C++ API. Similarly set `FC` to `xlF90` so that the Fortran APIs are built properly.)

By default, the netCDF library is built with assertions turned on. If you wish to turn off assertions, set `CPPFLAGS` to `-DNDEBUG` (csh ex: `setenv CPPFLAGS -DNDEBUG`).

If GNU compilers are used, the configure script sets `CPPFLAGS` to `"-g -O2"`. If this is not desired, set `CPPFLAGS` to nothing, or to whatever other value you wish to use, before running configure.

For cross-compiles, the following environment variables can be used to override the default fortran/C type settings like this (in sh):

```
export NCBYTE_T='integer(selected_int_kind(2))'
export NCSHORT_T='integer*2'
export NF_INT1_T='integer(selected_int_kind(2))'
export NF_INT2_T='integer*2'
export NF_INT1_IS_C_SHORT=1
export NF_INT2_IS_C_SHORT=1
export NF_INT_IS_C_INT=1
export NF_REAL_IS_C_FLOAT=1
export NF_DOUBLEPRECISION_IS_C_DOUBLE=1
```

In this case you will need to run configure with `-disable-fortran-compiler-check` and `-disable-fortran-type-check`.

### 3.2.1 Variable Description Notes

<code>CC</code>	C compiler	If you don't specify this, the configure script will try to find a suitable C compiler. The default choice is <code>gcc</code> . If you wish to use a vendor compiler you must set <code>CC</code> to that compiler, and set other environment variables (as described below) to appropriate settings.
<code>FC</code>	Fortran compiler (if any)	If you don't specify this, the configure script will try to find a suitable Fortran and Fortran 77 compiler. Set <code>FC</code> to "" explicitly, or provide the <code>-disable-f77</code> option to configure, if no Fortran interface (neither F90 nor F77) is desired. Use <code>-disable-f90</code> to disable the netCDF Fortran 90 API, but build the netCDF Fortran 77 API.

F77	Fortran compiler (if any)	77	Only specify this if your platform explicitly needs a different Fortran 77 compiler. Otherwise use FC to specify the Fortran compiler. If you don't specify this, the configure script will try to find a suitable Fortran compiler. For vendor compilers, make sure you're using the same vendor's Fortran 90 compiler. Using Fortran compilers from different vendors, or mixing vendor compilers with g77, the GNU F77 compiler, is not supported and may not work.
CXX	C++ compiler		If you don't specify this, the configure script will try to find a suitable C++ compiler. Set CXX to "" explicitly, or use the <code>--disable-cxx</code> configure option, if no C++ interface is desired. If using a vendor C++ compiler, use that vendor's C compiler to compile the C interface. Using different vendor compilers for C and C++ may not work.
CFLAGS	C compiler flags		"-O" or "-g", for example.
CPPFLAGS	C preprocessor options		"-DNDEBUG" to omit assertion checks, for example.
FCFLAGS	Fortran 90 compiler flags		"-O" or "-g", for example. These flags will be used for FORTRAN 90. If setting these you may also need to set FFLAGS for the FORTRAN 77 test programs.
FFLAGS	Fortran 77 compiler flags		"-O" or "-g", for example. If you need to pass the same arguments to the FORTRAN 90 build, also set FCFLAGS.
CXXFLAGS	C++ compiler flags		"-O" or "-g", for example.
ARFLAGS, NMFLAGS, FPP, M4FLAGS, LIBS, FLIBS, FLDFLAGS	Miscellaneous		One or more of these were needed for some platforms, as specified below. Unless specified, you should not set these environment variables, because that may interfere with the configure script.

The section marked Tested Systems below contains a list of systems on which we have built this package, the environment variable settings we used, and additional commentary.

### 3.3 Building on 64 Bit Platforms

The compiler options for SunOS, Irix, and AIX are listed below. The zlib and HDF5 libraries must also be built with 64-bit options.

AIX	Set -q64 option in all compilers, and set NMFLAGS to -X64, and ARFLAGS to '-X64 cru'. Alternatively, set environment variable OBJECT_MODE to 64 before running configure.
IRIX	Set the -64 option in all compilers.
SunOS	Use the -xarch=v9 or -m64 flag on all compilers for Sparc, or -m64 on x86 platforms.

### 3.4 Building on Platforms with Parallel I/O

NetCDF makes available the parallel I/O features of HDF5 and the parallel-netcdf libraries, allowing parallel I/O from netCDF-4 linked programs.

#### 3.4.1 Building HDF5 for Parallel I/O

For parallel I/O to work, HDF5 must be installed with `-enable-parallel`, and an MPI library (and related libraries) must be made available to the HDF5 configure. This can be accomplished with the `mpicc` wrapper script, in the case of MPICH2.

The following works to build HDF5 with parallel I/O on our netCDF testing system:

```
CC=mpicc ./configure --enable-parallel --prefix=/shecky/local_par --with-zlib=/shecky/
```

#### 3.4.2 The parallel-netcdf Library

Optionally, the parallel-netcdf library should also be installed, and the replacement for `pnetcdf.h` should be copied from `ftp://ftp.unidata.ucar.edu/pub/netcdf/contrib/pnetcdf.h`.

#### 3.4.3 Building NetCDF

To build netCDF with parallel I/O, build as usual, but point the configure at a version of HDF5 that has been built for parallel I/O.

```
CPPFLAGS=-I/shecky/local_par/include
CXXFLAGS=-I/shecky/local_par/include
FFLAGS=-I/shecky/local_par/include
FCFLAGS=-I/shecky/local_par/include LDFLAGS=-L/shecky/local_par/lib
FC=mpif90 CXX=mpicxx CC=mpicc ./configure
make check install
```

To enable the parallel tests, specify `-enable-parallel-tests` as an option to configure. These tests will be run as `mpiexec` calls. This may not be appropriate on all systems, especially those which use some queue for jobs.

To use parallel-netcdf to perform parallel I/O on classic and 64-bit offset files, use the `-enable-pnetcdf` option.

For parallel builds the netCDF examples are not built. This is to avoid cluttering them with `MPI_Init/Finalize` calls.

### 3.5 Running the configure Script

To create the Makefiles needed to build netCDF, you must run the provided configure script. Go to the top-level netCDF directory.

Decide where you want to install this package. Use this for the "--prefix=" argument to the configure script below. The default installation prefix is "/usr/local," which will install the package's files in usr/local/bin, usr/local/lib, and usr/local/man. The default can be overridden with the --prefix argument to configure.

Here's how to execute the configure script with a different installation directory:

```
./configure --prefix=/whatever/you/decided
```

The above would cause the netCDF libraries to be installed in /whatever/you/decided/lib, the header files in /whatever/you/decided/include, the utilities (ncdump/ncgen) in /whatever/you/decided/bin, and the man pages in /whatever/you/decided/man.

If the configure script finds HDF5 in the system directories, it will (attempt to) build the netCDF-4 enhanced features. To turn this off use the --disable-netcdf-4 option.

There are other options for the configure script. The most useful ones are listed below. Use the --help option to get the full list.

**--prefix** Specify the directory under which netCDF will be installed. Subdirectories lib, bin, include, and man will be created there, if they don't already exist.

**--disable-netcdf-4**

Turn off netCDF-4 features, even if HDF5 library is found.

**--disable-shared**

Build static libraries only.

**--enable-dap**

Enable DAP support. This flag is set by default if the configure script can locate a usable instance of the curl-config program. The curl-config program can be specified explicitly using --with-curl-config=/some/path/curl-config, or configure will attempt some heuristics to locate the curl-config program; typically by checking the PATH environment variable. If the flag --enable-dap flag is not set to either --enable-dap or --disable-dap, and a usable curl library can be found, then DAP support will be enabled by default. Note that when DAP is enabled, this can be tested for in a configure script by looking for the function "nc\_ropendap".

**--with-curl-config**

This flag may be used to specify the curl-config program so that DAP support can be enabled. Note that it should specify the actual program using something like --with-curl-config=/some/path/curl-config.

**--enable-dap-remote-tests**

If DAP support is enabled, then remote tests are run that utilize the test server at opendap.org. This option is enabled by default. Since that server may be inaccessible for a variety of reasons, these tests may fail, in which case this flag should be disabled.

**--enable-dap-long-tests**

If --enable-dap-remote-tests is enabled, then this flag can also be enabled to add extra tests that may take significant time to execute. This flag is off by default.

**--enable-hdf4**

Turns on the HDF4 read layer. This reads HDF4 files created with the SD (Scientific Data) API of HDF4.

**--enable-hdf4-file-tests**

Causes make check to use wget to fetch some HDF4 data files from the Unidata FTP server, and check that they are properly understood. This is done as part of automatic netCDF testing, and should not be done by users.

**--enable-pnetcdf**

Allows parallel I/O with classic and 64-bit offset format files, using the parallel-netcdf (formerly pnetcdf) library from Argonne/Northwestern. The parallel-netcdf library must be installed, and a specially modified pnetcdf.h must be used. (Get it at <ftp://ftp.unidata.ucar.edu/pub/netcdf/user/contrib/pnetcdf.h>)

**--with-udunits**

Builds UDUNITS2 as well as netCDF. The UDUNITS2 package supports units of physical quantities (e.g., meters, seconds). Specifically, it supports conversion between string and binary representations of units, arithmetic manipulation of units, and conversion of numeric values between compatible units. For more information about UDUNITS, see: <http://www.unidata.ucar.edu/software/udunits/>

**--disable-largefile**

This omits OS support for large files (i.e. files larger than 2 GB).

**--disable-fortran**

Turns off Fortran 77 and Fortran 90 API. (Same as `--disable-f77`.)

**--disable-f77**

This turns off building of the F77 and F90 APIs. (The F90 API cannot be built without the F77 API). This also disables some of the configure tests that relate to fortran, including the test of the F90 compiler. Setting the environment variables FC or F77 to NULL will have the same effect as `--disable-f77`.

**--disable-f90**

This turns off the building of the F90 API. Setting the environment variable F90 to null for configure will have the same effect.

**--disable-cxx**

This turns off the building of the C++ API. Setting the environment variable CXX to null for configure will have the same effect.

**--disable-v2**

This turns off the V2 API. The V2 API is completely replaced with the V3 API, but is usually built with netCDF for backwards compatibility, and also because the C++ API depends on the V2 API. Setting this has the effect of automatically turning off the CXX API, as if `--disable-cxx` had also been specified.

**--enable-cxx4**

Turns on the new C++ API, which is currently under development, and will expose the full expanded model in the C++ API. The cxx4 API is experimental, unfinished, and untested. It is provided for experimental purposes only.

**--enable-large-file-tests**

Turn on tests for large files. These tests create files over 2 GB in size, and need about 13 GB of free disk space to run. These files are deleted after the test successfully completes. They will be created in the netCDF `nc_test` directory, unless the `--with-temp-large` option is used to specify another location (see below).

**--with-temp-large**

Normally large files are not created during the netCDF build, but they will be if `--enable-large-file-tests` is specified (see above). In that case, this configure parameter can be used to specify a location to create these large files, for example: `--with-large-files=/tmp/ed`.

**--enable-benchmarks**

Turn on tests of the speed of various netCDF operations. Some of these operations take a long time to run (minutes, on a reasonable workstation).

**--enable-valgrind-tests**

Causes some tests to be re-run under valgrind, the memory testing tool. Valgrind must be present for this to work. Also HDF5 must be built with `--enable-using-memchecker`, and netCDF must be compiled without optimization (at least on the Unidata test platform where this is tested). The valgrind tests are run by shell script `libsrc4/run_valgrind_tests.sh`. It simply reruns the test programs in that directory, using valgrind, and with settings such that any error reported by valgrind will cause the “make check” to fail.

**--disable-fortran-type-check**

The netCDF configure compiles and runs some programs to test fortran vs. C type sizes. Setting this option turns off those test, and uses a set of default values (which can be overridden by environment variables see [Section 3.2 \[Environment\]](#), page 5).

**--disable-examples**

Starting with version 3.6.2, netCDF comes with some examples in the “examples” directory. By default, the examples are all built during a “make check” unless the `--disable-examples` option is provided.

**--enable-extra-tests**

This option may turn on tests which are known to fail (i.e. bugs that we are currently working to fix).

**--with-default-chunk-size**

Change the size (in bytes) that will be used as a target size when computing default chunk sizes for netCDF-4/HDF5 chunked variables.

**--default-chunks-in-cache**

Change the number of chunks that are accommodated in the per-variable chunk caches that are used by default.

- max-default-cache-size**  
Change the maximum size of the per-variable chunk caches that are used by default.
- with-chunk-cache-size**  
Change the size of the default file-level chunk cache size that will be used when opening netCDF-4/HDF5 files.
- with-chunk-cache-nelems**  
Change the size of the default file-level chunk cache number of elements that will be used when opening netCDF-4/HDF5 files. Should be a prime number.
- with-chunk-cache-preemption**  
Change the default preemption of the file-level chunk cache that will be used when opening netCDF-4/HDF5 files. Must be a number between 0 and 1 (inclusive).

The configure script will examine your computer system – checking for attributes that are relevant to building the netCDF package. It will print to standard output the checks that it makes and the results that it finds.

The configure script will also create the file "config.log", which will contain error messages from the utilities that the configure script uses in examining the attributes of your system. Because such an examination can result in errors, it is expected that "config.log" will contain error messages. Therefore, such messages do not necessarily indicate a problem (a better indicator would be failure of the subsequent "make"). One exception, however, is an error message in "config.log" that indicates that a compiler could not be started. This indicates a severe problem in your compilation environment – one that you must fix. If this occurs, configure will not complete and will exit with an error message telling you about the problem.

### 3.6 Running make

Run "make". This will build one or more netCDF libraries. It will build the basic netCDF library libnetcdf.a. If you have Fortran 77 or Fortran 90 compilers, then the Fortran library will also be built (libnetcdf.f.a). If you have a C++ compiler, then the C++ interface will be built (libnetcdf\_c++.a).

A “make” will also build the netCDF utilities ncgen(1) and ncdump(1).

Run make like this:

```
make
```

### 3.7 Testing the Build

Run “make check” to verify that the netCDF library and executables have been built properly (you can instead run “make test” which does the same thing).

A make check will build and run various test programs that test the C, Fortran, and C++ interfaces as well as the "ncdump" and "ncgen" utility programs.

Lines in the output beginning with "\*\*\*\*" report on success or failure of the tests; any failures will be reported before halting the test. Compiler and linker warnings during the testing may be ignored.

Run the tests like this:

```
make check
```

If you plan to use the 64-bit offset format (introduced in version 3.6.0) or the netCDF-4/HDF5 format to create very large files (i.e. with variables larger than 2 GB), you should probably specify the `--enable-large-file-tests` to configure, which tests the large file features. You must have 13 GB of free disk space for these tests to successfully run.

If you are running the large file tests, you may wish to use the `--with-temp-large` option to specify a temporary directory for the large files. (You may also set the environment variable `TEMP_LARGE` before running configure).

The default is to create the large files in the `nc_test` subdirectory of the netCDF build.

Run the large file tests like this:

```
./configure --enable-large-file-tests --with-temp-large=/home/ed/tmp
make check
```

All of the large files are removed on successful completion of tests. If the test fails, you may wish to make sure that no large files have been left around.

If any of the the large file tests test fail, check to ensure that your file system can handle files larger than 2 GiB by running the following command:

```
dd if=/dev/zero bs=1000000 count=3000 of=$(TEMP_LARGE)/largefile
```

If your system does not have a `/dev/zero`, this test will fail. Then you need to find some other way to create a file larger than 2 GiB to ensure that your system can handle them.

See [Chapter 6 \[Build Problems\]](#), page 27.

## 3.8 Installing NetCDF

To install the libraries and executables, run "make install". This will install to the directory specified in the configure step.

Run the installation like this:

```
make install
```

The install will put files in the following subdirectories of the directory you provided as a prefix, creating the subdirectories if needed:

**lib** Libraries will be installed here. If static libraries are built, without separate fortran libraries, then `libnetcdf.a` and `libnetcdf.la` will be installed. If the C++ API is built, `libnetcdf_c++.a` and `libnetcdf_c++.la` will be added. If separate fortran libraries are built, `libnetcdf_f.a` and `libnetcdf_f.la` will also be added.

Static library users should ignore the `.la` files, and link to the `.a` files.

Shared library builds will add some `.so` files to this directory, as well.

**include** Header files will be installed here. The C library header file is `netcdf.h`. If the C++ library is built, `netcdfcpp.h`, `ncvalues.h` and `netcdf.hh` will be installed here. If the F77 API is built, `netcdf.inc` will be copied here. If the F90 API is built, the `netcdf.mod` and `typesizes.mod` files will be copied here as well.

**bin** Utilities `ncdump` and `ncgen` will be installed here.

- man** The ncdump/ncgen man pages will be installed in subdirectory man1, and the three man pages netcdf.3, netcdf\_f77.3, and netcdf\_f90.3 will be installed in the man3 subdirectory.
- share** If the configure is called with the `--enable-docs` option, the netCDF documentation set will be built, and will be installed under the share directory, under the netcdf subdirectory. This will include postscript, PDF, info and text versions of all netCDF manuals. These manuals are also available at the netCDF web site.

Try linking your applications. Let us know if you have problems (see [Section 6.4 \[Reporting Problems\]](#), page 30).

## 3.9 Platform Specific Notes

The following platform-specific note may be helpful when building and installing netCDF. Consult your vendor manuals for information about the options listed here. Compilers can change from version to version; the following information may not apply to your platform.

Full output from some of the platforms of the test platforms for netCDF 4.1.3-beta1 can be found at <http://www.unidata.ucar.edu/netcdf/builds>.

### 3.9.1 AIX

We found the vendor compilers in `/usr/vac/bin`, and included this in our PATH. Compilers were xlc, xlf, xlf90, x1C.

The F90 compiler requires the `qsuffix` option to believe that F90 code files can end with `.f90`. This is automatically turned on by `configure` when needed:

```
FCFLAGS=-qsuffix=f=f90
```

We had to use xlf for F77 code, and xlf90 for F90 code.

To compile 64-bit code, set the appropriate environment variables (documented below).

The environment variable `OBJECT_MODE` can be set to 64, or use the `-q64` option on all AIX compilers by setting `CFLAGS`, `FFLAGS`, and `CXXFLAGS` to `-q64`.

The following is also necessary on an IBM AIX SP system for 64-bit mode:

```
ARFLAGS='-X64 cru'
NMFLAGS='-X64'
```

There are thread-safe versions of the AIX compilers. For example, `xlc_r` is the thread-safe C compiler. To use thread-safe compilers, override the `configure` script by setting `CC` to `xlc_r`; similarly for `FC` and `CXX`.

For large file support, AIX requires that the macro `_LARGE_FILES` be defined. The `configure` script does this using `AC_SYS_LARGEFILES`. Unfortunately, this misfires when `OBJECT_MODE` is 64, or the `q64` option is used. The netCDF tries to fix this by turning on `_LARGE_FILES` anyway in these cases.

The GNU C compiler does not mix successfully with the AIX fortran compilers.

### 3.9.2 Cygwin

NetCDF builds under Cygwin tools on Windows just as with Linux.

### 3.9.3 HPUX

The HP Fortran compiler (f77, a.k.a. fort77, also f90) requires FLIBS to include -lU77 for the fortran tests to work. The configure script does this automatically.

For the c89 compiler to work, CPPFLAGS must include -D\_HPUX\_SOURCE. This isn't required for the cc compiler. The configure script adds this as necessary.

For large file support, HP-UX requires \_FILE\_OFFSET\_BITS=64. The configure script sets this automatically.

The HPUX C++ compiler doesn't work on netCDF code. It's too old for that. So either use GNU to compile netCDF, or skip the C++ code by setting CXX to "" (in csh: setenv CXX "").

Building a 64 bit version may be possible with the following settings:

```
CC=/bin/cc
CPPFLAGS='-D_HPUX_SOURCE -D_FILE_OFFSET_BITS=64'    # large file support
CFLAGS='-g +DD64'                                  # 64-bit mode
FC=/opt/fortran90/bin/f90                          # Fortran-90 compiler
FFLAGS='-w +noppu +DA2.0W'                         # 64-bit mode, no "_" suffixes
FLIBS=-lU77
CXX=''                                              # no 64-bit mode C++ compiler
```

Sometimes quotas or configuration causes HPUX disks to be limited to 2 GiB files. In this cases, netCDF cannot create very large files. Rather confusingly, HPUX returns a system error that indicates that a value is too large to be stored in a type. This may cause scientists to earnestly check for attempts to write floats or doubles that are too large. In fact, the problem seems to be an internal integer problem, when the netCDF library attempts to read beyond the 2 GiB boundary. To add to the confusion, the boundary for netCDF is slightly less than 2 GiB, since netCDF uses buffered I/O to improve performance.

### 3.9.4 Irix

A 64-bit version can be built by setting the appropriate environment variables.

Build 64-bit by setting CFLAGS, FFLAGS, and CXXFLAGS to -64.

On our machine, there is a /bin/cc and a /usr/bin/cc, and the -64 option only works with the former.

### 3.9.5 Linux

The gFortran flag is required with GNU fortran:

```
CPPFLAGS=-DgFortran
```

For Portland Group Fortran, set pgiFortran instead:

```
CPPFLAGS=-DpgiFortran
```

Portland Group F90/F95 does not mix with GNU g77.

The netCDF configure script should notice which fortran compiler is being used, and set these automatically.

For large file support, \_FILE\_OFFSET\_BITS must be set to 64. The netCDF configure script should set this automatically.

### 3.9.6 Macintosh

The gFortran flag is required with GNU fortran (CPPFLAGS=-DgFortran). The NetCDF configure script should and set this automatically.

For IBM compilers on the Mac, the following may work (we lack this test environment):

```
CC=/usr/bin/cc
CPPFLAGS=-DIBMR2Fortran
F77=xlf
FC=xlf90
FCFLAGS=-qsuffix=cpp=f90
```

### 3.9.7 OSF1

NetCDF builds out of the box on OSF1.

### 3.9.8 SunOS

PATH should contain /usr/ccs/bin to find make, nm, ar, etc.

For large file support, `_FILE_OFFSET_BITS` must be 64, also `_LARGEFILE64_SOURCE` and `_LARGEFILE_SOURCE` must be set. Configure will turn this on automatically for netCDF, but not for HDF5. So when building HDF5, set these variables before running configure, or HDF5 will not be capable of producing large files.

To compile in 64-bit mode, set `-m64` (formerly `-xarch=v9`, which works on SPARC platforms only) on all compilers (i.e. in `CFLAGS`, `FFLAGS`, `FCFLAGS`, and `CXXFLAGS`).

When compiling with GNU Fortran (g77), the `-DgFortran` flag is required for the Fortran interface to work. The NetCDF configure script turns this on automatically if needed.

### 3.9.9 Handling Fortran Compilers

Commercial fortran compilers will generally require at least one flag in the `CPPFLAGS` variable. The netCDF configure script tries to set this for you, but won't try if you have used `--disable-flag-setting`, or if you have already set `CPPFLAGS`, `CFLAGS`, `CXXFLAGS`, `FCFLAGS`, or `FFLAGS` yourself.

The first thing to try is to set nothing and see if the netCDF configure script finds your fortran compiler, and sets the correct flags automatically.

If it doesn't find the correct fortran compiler, you can next try setting the `FC` environment variable to the compiler you wish to use, and then see if the configure script can set the correct flags for that compiler.

If all that fails, you must set the flags yourself.

The Intel compiler likes the `pgiFortran` flag, as does the Portland Group compiler. (Automatically turned on if your fortran compiler is named "ifort" or "pgf90").

Alternatively, Intel has provided a web page on "Building netCDF with the Intel compilers" at <http://www.intel.com/support/performance/tools/sb/CS-027812.htm>, providing instructions for building netCDF (without using the `pgiFortran` flag).

The Portland Group also has a "PGI Guide to NetCDF" at <http://www.pgroup.com/resources/netcdf/netcdf71.htm>.

### 3.10 Additional Porting Notes

The configure and build system should work on any system which has a modern "sh" shell, "make", and so on. The configure and build system is less portable than the "C" code itself, however. You may run into problems with the "include" syntax in the Makefiles. You can use GNU make to overcome this, or simply manually include the specified files after running configure.

Instruction for building netCDF on other platforms can be found at <http://www.unidata.ucar.edu/netcdf/other-builds.html>. If you build netCDF on a new platform, please send your environment variables and any other important notes to support-netcdf@unidata.ucar.edu and we will add the information to the other builds page, with a credit to you.

If you can't run the configure script, you will need to create config.h and fortran/nfconfig.inc. Start with ncconfig.in and fortran/nfconfig.in and set the defines as appropriate for your system.

Operating system dependency is isolated in the "ncio" module. We provide two versions. posixio.c uses POSIX system calls like "open()", "read()" and "write()". fpio.c uses a special library available on CRAY systems. You could create other versions for different operating systems. The program "t\_ncio.c" can be used as a simple test of this layer.

Note that we have not had a Cray to test on for some time. In particular, large file support is not tested with fpio.c.

Numerical representation dependency is isolated in the "ncx" module. As supplied, ncx.m4 (ncx.c) supports IEEE floating point representation, VAX floating point, and CRAY floating point. BIG\_ENDIAN vs LITTLE\_ENDIAN is handled, as well as various sizes of "int", "short", and "long". We assume, however, that a "char" is eight bits.

There is a separate implementation of the ncx interface available as ncx\_cray.c which contains optimizations for CRAY vector architectures. Move the generic ncx.c out of the way and rename ncx\_cray.c to ncx.c to use this module. By default, this module does not use the IEG2CRAY and CRAY2IEG library calls. When compiled with aggressive in-lining and optimization, it provides equivalent functionality with comparable speed and clearer error semantics. If you wish to use the IEG library functions, compile this module with -DUSE\_IEG.

### 3.11 Contributing to NetCDF Source Code Development

Most users will not be interested in working directly with the netCDF source code. Rather, they will write programs which call netCDF functions, and delve no further. However some intrepid users may wish to dig into the netCDF code to study it, to try and spot bugs, or to make modifications for their own purposes.

To work with the netCDF source code, several extra utilities are required to fully build everything from source. If you are going to modify the netCDF source code, you will need some or all of the following Unix tools.

**m4** Macro processing language used heavily in libsrc, nc\_test. Generates (in these cases) C code from m4 source. Version 1.4 works fine with release 3.5.1 through 3.6.2.

**flex and yacc**

Used in `ncgen` directory to parse CDL files. Generates C files from `.y` and `.l` files. You only need to use this to modify `ncgen`'s understanding of CDL grammar.

**makeinfo** Generates all documentation formats (except man pages) from `texinfo` source. I'm using `makeinfo` version 4.8, as of release 3.6.2. If you have trouble with `makeinfo`, upgrade to this version and try again. You only need `makeinfo` if you want to modify the documentation.

**tex** Knuth's venerable typesetting system. The version I am running (for `netCDF` release 3.6.2) is `TeX 3.141592 (Web2C 7.5.4)`. I have found that some recent installations of `TeX` will not build the `netCDF` documentation - it's not clear to me why.

The user generally will just want to download the latest version of `netCDF` documents at the `netCDF` website. <http://www.unidata.ucar.edu/netcdf/docs>.

**autoconf** Generates the configure script. Version 2.59 or later is required.

**automake** Since version 3.6.2 of `netCDF`, `automake` is used to generate the `Makefile.in` files needed by the configure script to build the `Makefiles`.

**libtool** Since version 3.6.2 of `netCDF`, `libtool` is used to help generate shared libraries platforms which support them. Version 2.1a of `libtool` is required.

**sed** This text processing tool is used to process some of the `netCDF` examples before they are included in the tutorial. This is only needed to build the documentation, which the user generally will not need to do.

`NetCDF` has a large and enterprising user community, and a long history of accepting user modifications into the `netCDF` code base. Examples include the 64-bit offset format, and the F90 API.

All suggested changes and additions to `netCDF` code can be sent to `support-netcdf@unidata.ucar.edu`.

## 4 Using NetCDF on Unix Systems

To use netCDF you must link to the netCDF library, and, if using the netCDF-4/HDF5 features, also two HDF5, at least one compression library, and (on some systems) the math library.

### 4.1 Using Linker Flags with NetCDF

For this to work, you have to tell the linker which libraries to link to (with the `-l` option), and where to find them (with the `-L` option).

Use the `-L` option to your linker to pass the directories in which netCDF, HDF5, and zlib are installed.

Use the `-l` (lower-case L) option to list the libraries, which must be listed in the correct order:

```
-lnetcdf -lhdf5_hl -lhdf5 -lz -lm
```

If `zip` was used when building HDF5, you must also use `-lsz`.

On some systems you must also include `-lm` for the math library.

If HDF4 was used when building netCDF, you must also use `-lmfhdf -ldf -ljpeg`.

Finally, if you use the `parallel-netcdf` library, you must use `-lpnetcdf`.

The worst case scenario is, using all of the above libraries:

```
-lnetcdf -lpnetcdf -lmfhdf -ldf -ljpeg -lhdf5_hl -lhdf5 -lz -lsz -lm
```

In such a case one also needs to provide the locations of the libraries, with the `-L` flag. If libraries are installed in the same directory, this is easier.

Use the `nc-config` to learn the exact flags needed on your system (see [Section 4.3 \[nc-config\]](#), page 19).

### 4.2 Using Compiler Flags with NetCDF

Depending on how netCDF was built, you may need to use compiler flags when building your code. For example, many systems build both 32-bit and 64-bit binaries. The GNU C compiler, for example, uses `-m32` and `-m64` as compiler flags for this purpose.

If netCDF is built with the default compiler flags (i.e. no special flags are used), then no flags need to be used by the user.

If netCDF is built using flags that control architecture or other important aspects of the binary output, then those flags may need to be set by all users as well.

### 4.3 Using the nc-config Utility to Find Compiler and Linker Flags

To assist with the setting of compiler and linker flags, the `nc-config` utility is provided with netCDF. The `nc-config` utility is a very simple script which contains the settings of the C and Fortran flags used during the netCDF build.

For example, the `nc-config` command can be used to get the command line options needed to link a C program to netCDF:

```
nc-config --libs  
-L/usr/local/lib -lnetcdf -L/shecky/local_post/lib -lhdf5_hl -lhdf5 -lz
```

The `nc-config` utility can also be used to learn about the features of the current netCDF installation. For example, it can show whether netCDF-4 is available:

```
./nc-config --has-nc4  
yes
```

Use the `-help` option to `nc-config` for a full list of available information.

## 5 Building and Installing NetCDF on Windows

NetCDF can be built and used from a variety of development environments on Windows. The netCDF library is implemented as a Windows dynamic link library (DLL). The simplest way to get started with netCDF under Windows is to download the pre-built DLL from the Unidata web site.

Building under the Cygwin port of GNU tools is treated as a Unix install. See [Section 3.9 \[Platform Notes\]](#), page 14.

Instructions are also given for building the netCDF DLL from the source code.

VC++ documentation being so voluminous, finding the right information can be a chore. There's a good discussion of using DLLs called "About Dynamic-Link Libraries" at (perhaps) [http://msdn.microsoft.com/library/default.asp?url=/library/en-us/dllproc/base/dynamic\\_link\\_libraries.asp](http://msdn.microsoft.com/library/default.asp?url=/library/en-us/dllproc/base/dynamic_link_libraries.asp).

From the .NET point of view, the netCDF dll is unmanaged code. As a starting point, see the help topic "Consuming Unmanaged DLL Functions" which may be found at <http://msdn.microsoft.com/library/default.asp?url=/library/en-us/cpguide/html/cpconConsumin>, unless the page has been moved.

### 5.1 Getting Prebuilt netcdf.dll

We have pre-built Win32 binary versions of the netcdf dll and static library, as well as ngen.exe and ncdump.exe (dll and static versions). You can get them from <ftp://ftp.unidata.ucar.edu/pub/netcdf/contrib/win32/netcdf-3.6.1-beta1-win32dll.zip>. (Note: we don't have a C++ interface here).

### 5.2 Installing the DLL

Whether you get the pre-built DLL or build your own, you'll then have to install it somewhere so that your other programs can find it and use it.

To install a DLL, you just have to leave it in some directory, and (possibly) tell your compiler in which directory to look for it.

A DLL is a library, and functions just like libraries under the Unix operating system. As with any library, the point of the netCDF DLL is to provide functions that you can call from your own code. When you compile that code, the linker needs to be able to find the library, and then it pulls out the functions that it needs. In the Unix world, the `-L` option tells the compiler where to look for a library. In Windows, library search directories can be added to the project's property dialog.

Similarly, you will need to put the header file, `netcdf.h`, somewhere that your compiler can find it. In the Unix world, the `-I` option tells the compiler to look in a certain directory to find header files. In the Windows world, you set this in the project properties dialog box of your integrated development environment.

Therefore, installing the library means nothing more than copying the DLL somewhere that your compiler can find it, and telling the compiler where to look for them.

The standard place to put DLLs is `Windows\System32` folder (for Windows2000/XP) or the `Windows\System` folder (for Windows 98/ME). If you put the DLL there, along with

the `ncgen` and `ncdump` executables, you will be able to use the DLL and utilities without further work, because compilers already look there for DLLs and EXEs.

Instead of putting the DLL and EXEs into the system directory, you can leave them wherever you want, and every development project that uses the dll will have to be told to search the netCDF directory when it's linking, or, the chosen directory can be added to your path.

On the .NET platform, you can also try to use the global assembly cache. (To learn how, see MSDN topic "Global Assembly Cache", at [www.msdn.microsoft.com](http://www.msdn.microsoft.com)).

Following Windows conventions, the netCDF files belong in the following places:

File(s)	Description	Location
<code>netcdf.dll</code>	C and Fortran function in DLL	Windows\System (98/ME) or Windows\System32 (2000/XP)
<code>netcdf.lib</code>	Library file	Windows\System (98/ME) or Windows\System32 (2000/XP)
<code>ncgen.exe</code> , <code>ncdump.exe</code>	NetCDF utilities	Windows\System (98/ME) or Windows\System32 (2000/XP)
<code>netcdf-3</code>	netCDF source code	Program Files\Unidata

### 5.3 Building netcdf.dll with VC++ 6.0

The most recent releases of netCDF aren't tested under VC++ 6.0. (They are tested with VC++.NET). Older versions of the library, notably 3.5.0, did compile with VC++ 6.0, and the instructions for doing so are presented below.

Note that the introduction of better large file support (for files larger than 2 GiB) in version 3.6.0 and greater requires an `off_t` type of 8 bytes, and it's not clear how, or if, this can be found in VC++ 6.0.

To build the library yourself, get the file <ftp://ftp.unidata.ucar.edu/pub/netcdf/contrib/win32/netcdf-3.5.0.win32make.VC6.zip>

The makefiles there describe how to build `netcdf-3.5` using the using Microsoft Visual C++ 6.x and (optionally) Digital Visual Fortran 6.x. Because of difficulties in getting Microsoft Visual Studio to fall in line with our existing source directory scheme, we chose `_not_` to build the system "inside" Visual Studio. Instead, we provide a simple group of "msoft.mak"

files which can be used. If you wish to work in Visual Studio, go ahead. Read the section called "Macros" at the end of this discussion.

As of this writing, we have not tried compiling the C++ interface in this environment.

`nmake` is a Microsoft version of `make`, which comes with VC 6.0 (and VC 7.0) in directory `C:\Program Files\Microsoft Visual Studio\VC98\Bin` (or, for VC 7.0, `C:\Program Files\Microsoft Visual Studio .NET 2003\Vc7\bin`).

To build `netcdf`, proceed as follows:

`unpack source distribution.`

`copy netcdf-3.5.0.win32make.VC6.zip`

copy `netcdf-3.5.0.win32make.VC6.zip` into the `netcdf-3.5.0/src` directory, and unzip it from there.

`cd src\libsrc; nmake /f msoft.mak`

Run this command in `src\libsrc`. This will build `netcdf.lib` and `netcdf.dll` Note: This makefiles make DLLs. To make static libraries see section on static libraries.

`nmake /f msoft.mak test`

Optionally, in `src\libsrc`, make and run the simple test.

`cd ..\fortran; nmake /f msoft.mak`

Optionally build the fortran interface and rebuild dll in `..\libsrc` to include the fortran interface. Note Bene: We don't provide a `.DEF` file, so this step changes the "ordinals" by which entry points in the DLL found. Some sites may wish to modify the `msoft.mak` file(s) to produce a separate library for the fortran interface.

`nmake /f msoft.mak test`

(necessary if you want to use fortran code) While you are in `src\fortran`; `nmake /f msoft.mak test` This tests the `netcdf-2` fortran interface.

`cd ..\nctest; nmake /f msoft.mak test`

(optional, but recommended) In `src\nctest`; `nmake /f msoft.mak test` This tests the `netcdf-2` C interface.

`cd ..\nc_test; nmake /f msoft.mak test`

(optional, but highly recommended) In `src\nc_test`; `nmake /f msoft.mak test` This tortures the `netcdf-3` C interface.

`cd ..\nf_test; nmake /f msoft.mak test`

(optional, but highly recommended if you built the fortran interface) In `src\nf_test`; `nmake /f msoft.mak test` This tortures the `netcdf-3` fortran interface.

`..\ncdump; nmake /f msoft.mak`

In `src\ncdump`; `nmake /f msoft.mak` This makes `ncdump.exe`.

`..\ncgen; nmake /f msoft.mak`

In `src\ncgen`; `nmake /f msoft.mak` This makes `ncgen.exe`.

```
..\ncdump; nmake /f msoft.mak test
```

(optional) In src\ncdump; nmake /f msoft.mak test This tests ncdump. Both ncgen and ncdump need to be built prior to this test. Note the makefile sets the path so that ..\libsrc\netcdf.dll can be located.

```
..\ncgen; nmake /f msoft.mak test
```

(optional) In src\ncgen; nmake /f msoft.mak test This tests ncgen. Both ncgen and ncdump need to be built prior to this test. Note the makefile sets the path so that ..\libsrc\netcdf.dll can be located.

#### To Install

Copy libsrc\netcdf.lib to a LIBRARY directory. Copy libsrc\netcdf.h and fortran/netcdf.inc to an INCLUDE directory. Copy libsrc\netcdf.dll, ncdump/ncdump.exe, and ncgen/ncgen.exe to a BIN directory (someplace in your PATH).

## 5.4 Using netcdf.dll with VC++ 6.0

To use the netcdf.dll:

1. Place these in your include directory: netcdf.h C include file netcdf.inc Fortran include file

- 2a. To use the Dynamic Library (shared) version of the netcdf library: Place these in a directory that's in your PATH: netcdf.dll library dll ncgen.exe uses the dll ncdump.exe uses the dll

Place this in a library directory to link against: netcdf.lib library

- 2b. Alternatively, to use a static version of the library

Place this in a library directory to link against: netcdfs.lib library

Place these in a directory that's in your PATH: ncgens.exe statically linked (no DLL needed) ncdumps.exe statically linked (no DLL needed)

## 5.5 Building netcdf.dll with VC++.NET

To build the netCDF dll with VC++.NET open the win32/NET/netcdf.sln file with Visual Studio. Both Debug and Release configurations are available - select one and build.

The resulting netcdf.dll file will be in subdirectory Release or Debug.

The netCDF tests will be built and run as part of the build process. The Fortran 77 interface will be built, but not the Fortran 90 or C++ interfaces.

Unfortunately, different fortran compilers require different flag settings in the netCDF configuration files. (In UNIX builds, this is handled by the configure script.)

The quick\_large\_files test program is provided as an extra project, however it is not run during the build process, but can be run from the command line or the IDE. Note that, despite its name, it is not quick. On Unix systems, this program runs in a few seconds, because of some features of the Unix file system apparently not present in Windows. Nonetheless, the program does run, and creates (then deletes) some very large files. (So make sure you have at least 15 GiB of space available). It takes about 45 minutes to run this program on our Windows machines, so please be patient.

## 5.6 Using netcdf.dll with VC++.NET

Load-time linking to the DLL is the most straightforward from C++. This means the netcdf.lib file has to end up on the compile command line. This being Windows, that's hidden by a GUI.

In Visual Studio 2003 this can be done by modifying three of the project's properties.

Open the project properties window from the project menu. Go to the linker folder and look at the general properties. Modify the property "Additional Library Directories" by adding the directory which contains the netcdf.dll and netcdf.lib files. Now go to the linker input properties and set the property "Additional Dependencies" to netcdf.lib.

Finally, still within the project properties window, go to the C/C++ folder, and look at the general properties. Modify "Additional Include Directories" to add the directory with the netcdf.h file.

Now use the netCDF functions in your C++ code. Of course any C or C++ file that wants to use the functions will need:

```
#include <netcdf.h>
```

## 6 If Something Goes Wrong

The netCDF package is designed to build and install on a wide variety of platforms, but doesn't always. It's a crazy old world out there, after all.

### 6.1 The Usual Build Problems

#### 6.1.1 Taking the Easy Way Out

Why not take the easy way out if you can?

Many Linux systems contain package management programs which allow netCDF to be installed easily. This is the preferred installation method for netCDF.

Precompiled binaries for some platforms can be found at <http://www.unidata.ucar.edu/downloads/netcdf>. Click on your platform, and copy the files from the bin, include, lib, and man directories into your own local equivalents (Perhaps /usr/local/bin, /usr/local/include, etc.).

#### 6.1.2 How to Clean Up the Mess from a Failed Build

If you are trying to get the configure or build to work, make sure you start with a clean distribution for each attempt. If netCDF failed in the “make” you must clean up the mess before trying again. To clean up the distribution:

```
make distclean
```

#### 6.1.3 Platforms On Which NetCDF is Known to Work

At NetCDF World Headquarters (in sunny Boulder, Colorado), as part of the wonderful Unidata organization, we have a wide variety of computers, operating systems, and compilers. At night, house elves test netCDF on all these systems.

Output for the netCDF test platforms can be found at <http://www.unidata.ucar.edu/netcdf/builds>.

Compare the output of your build attempt with ours. Are you using the same compiler? The same flags? Look for the configure output that lists the settings of CC, FC, CXX, CFLAGS, etc.

On some systems you have to set environment variables to get the configure and build to work.

For example, for a 64-bit IRIX install of the netCDF-3.6.2 release, the variables are set before netCDF is configured or built. In this case we set CFLAGS, CXXFLAGS, FCFLAGS, and FFLAGS.

```
flip% uname -a
IRIX64 flip 6.5 07080050 IP30 mips
flip% setenv CFLAGS -64
flip% setenv CXXFLAGS -64
flip% setenv FFLAGS -64
flip% setenv FCFLAGS -64
flip% make distclean;./configure;make check
```

### 6.1.4 Platforms On Which NetCDF is Reported to Work

If your platform isn't listed on the successful build page, see if another friendly netCDF user has sent in values for environment variables that are reported to work: (<http://www.unidata.ucar.edu/netcdf/other-builds.html>).

If you build on a system that we don't have at Unidata (particularly if it's something interesting and exotic), please send us the settings that work (and the entire build output would be nice too). Send them to [support-netcdf@unidata.ucar.edu](mailto:support-netcdf@unidata.ucar.edu).

### 6.1.5 If You Have a Broken Compiler

For netCDF to build correctly, you must be able to compile C from your environment, and, optionally, Fortran 77, Fortran 90, and C++. If C doesn't work, netCDF can't compile.

What breaks a C compiler? Installation or upgrade mistakes when the C compiler was installed, or multiple versions or compilers installed on top of each other. Commercial compilers frequently require some environment variables to be set, and some directories to appear ahead of others in your path. Finally, if you have an expired or broken license, your C compiler won't work.

If you have a broken C compiler and a working C compiler in your PATH, netCDF might only find the broken one. You can fix this by explicitly setting the CC environmental variable to a working C compiler, and then trying to build netCDF again. (Don't forget to do a "make distclean" first!)

If you can't build a C program, you can't build netCDF. Sorry, but that's just the way it goes. (You can get the GNU C compiler - search the web for "gcc").

If netCDF finds a broken Fortran 90, Fortran 77, or C++ compiler, it will report the problem during the configure, and then drop the associated API. For example, if the C++ compiler can't compile a very simple test program, it will drop the C++ interface. If you really want the C++ API, set the CXX environment variable to a working C++ compiler.

### 6.1.6 What to Do If NetCDF Still Won't Build

If none of the above help, try our troubleshooting section: See [Section 6.2 \[Troubleshooting\]](#), [page 28](#).

Also check to see if your problem has already been solved by someone else (see [Section 6.3 \[Finding Help\]](#), [page 30](#)).

If you still can't get netCDF to build, report your problem to Unidata, but please make sure you submit all the information we need to help (see [Section 6.4 \[Reporting Problems\]](#), [page 30](#)).

## 6.2 Troubleshooting

### 6.2.1 Problems During Configuration

If the `./configure; make check` fails, it's a good idea to turn off the C++ and Fortran interfaces, and try to build the C interface alone. All other interfaces depend on the C interface, so nothing else will work until the C interface works. To turn off C++ and Fortran, set environment variables CXX and FC to NULL before running the netCDF configure script (with `csh: setenv FC "";setenv CXX ""`).

Turning off the Fortran and C++ interfaces results in a much shorter build and test cycle, which is useful for debugging problems.

If the netCDF configure fails, most likely the problem is with your development environment. The configure script looks through your path to find all the tools it needs to build netCDF, including C compiler and linker, the ar, ranlib, and others. The configure script will tell you what tools it found, and where they are on your system. Here's part of configure's output on a Linux machine:

```
checking CPPFLAGS...
checking CC CFLAGS... cc -g -O2
checking type cc... cc is /usr/bin/cc
checking CXX... c++
checking CXXFLAGS... -g -O2
checking type c++... c++ is /usr/bin/c++
checking FC... gfortran
checking FFLAGS... -g -O2
checking type gfortran... gfortran is /usr/bin/gfortran
checking F90... gfortran
checking FCFLAGS... -g -O2
checking type gfortran... gfortran is /usr/bin/gfortran
checking AR... ar
checking AR_FLAGS... cru
checking type ar... ar is /usr/bin/ar
checking NM... /usr/bin/nm -B
checking NMFLAGS...
checking for /usr/bin/nm... /usr/bin/nm -B
checking nm flags...
```

Make sure that the tools, directories, and flags are set to reasonable values, and compatible tools. For example the GNU tools may not inter-operate well with vendor tools. If you're using a vendor compiler, you may need to use the ar, nm, and ranlib that the vendor supplied.

As configure runs, it creates a config.log file. If configure crashes, do a text search of config.log for thing it was checking before crashing. If you have a licensing or tool compatibility problem, it will be obvious in config.log.

### 6.2.2 Problems During Compilation

If the configure script runs, but the compile step doesn't work, or the tests don't complete successfully, the problem is probably in your CFLAGS or CPPFLAGS.

Frequently shared libraries are a rich source of problems. If your build is not working, and you are using the `-enable-shared` option to generate shared libraries, then try to build without `-enable-shared`, and see if the static library build works.

### 6.2.3 Problems During Testing

If you are planning on using large files (i.e. > 2 GiB), then you may wish to rerun configure with `-enable-large-file-tests` to ensure that large files work on your system.

Some DAP tests (in the directory `ncdap_test`) attempt to access an external server at `opendap.org`. It is possible that the DAP server may not be running at test time, or the

network access may be faulty or that the output of the test server has changed. In this case, the DAP tests may fail. Because of this, the use of these tests is controlled by the `-enable-dap-remote-tests` option.

## 6.3 Finding Help On-line

The latest netCDF documentation (including this manual) can be found at <http://www.unidata.ucar.edu/netcdf/docs>.

The output of successful build and test runs for recent versions of netCDF can be found at <http://www.unidata.ucar.edu/netcdf/builds>.

A list of known problems with netCDF builds, and suggested fixes, can be found at [http://www.unidata.ucar.edu/netcdf/docs/known\\_problems.html](http://www.unidata.ucar.edu/netcdf/docs/known_problems.html).

Reportedly successful settings for platforms unavailable for netCDF testing can be found at <http://www.unidata.ucar.edu/netcdf/other-builds.html>. If you build netCDF on a system that is not listed, please send your environment settings, and the full output of your configure, compile, and testing, to [support-netcdf@unidata.ucar.edu](mailto:support-netcdf@unidata.ucar.edu). We will add the information to the other-builds page, with a credit to you.

The replies to all netCDF support emails are on-line and can be searched. Before reporting a problem to Unidata, please search this on-line database to see if your problem has already been addressed in a support email. If you are having build problems it's usually useful to search on your system host name. On Unix systems, use the `uname` command to find it.

The netCDF Frequently Asked Questions (FAQ) list can be found at <http://www.unidata.ucar.edu/netcdf/faq.html>.

To search the support database, see `/search.jsp?support&netcdf`.

The netCDF mailing list also can be searched; see `/search.jsp?netcdfgroup`.

## 6.4 Reporting Problems

To help us solve your problem, please include the following information in your email to [support-netcdf@unidata.ucar.edu](mailto:support-netcdf@unidata.ucar.edu).

Unfortunately, we can't solve build questions without this information; if you ask for help without providing it, we're just going to have to ask for it.

So why not send it immediately, and save us both the extra trouble?

1. the exact version of netCDF - see the VERSION file.
2. the \*complete\* output of `./configure`, `make`, and `make check`. Yes, it's long, but it's all important.
3. if the configure failed, the contents of `config.log`.
4. if you are having problems with very large files (larger than 2GiB), send the output of "make check" after first running "make distclean" and invoking the configure script with the `-enable-large-file-tests` option included.

Although responses to your email will be available in our support database, your email address is not included, to provide spammers with one less place to harvest it from.
