Data-Intensive Science and Scientific Data Infrastructure

Russ Rew, UCAR Unidata
ICTP Advanced School on High Performance and Grid Computing
13 April 2011
Overview

• Data-intensive science
• Example: model outputs for IPCC AR5
• Publishing scientific data
Data-intensive science

• A “fourth paradigm” after experiment, theory, and computation

• Involves collecting, exploring, visualizing, combining, subsetting, analyzing, and using huge data collections

• Challenges include
  – Deluge of observational data, “exaflood” of simulation model outputs
  – Need for collaboration among groups, disciplines, communities
  – Finding insights and discoveries in a “Sea of Data”

• Data-intensive science requires
  – New tools, techniques, and infrastructure
  – Standards for interoperability
  – Institutional support for data stewardship, curation
Roles in Data-intensive Science

• **Scientists/researchers:** acquire, generate, analyze, check, organize, format, document, share, publish research data

• **Data users:** access, understand, integrate, visualize, analyze, subset, and combine data

• **Data scientists:** develop infrastructure, standards, conventions, frameworks, data models, Web-based technologies

• **Software developers:** develop tools, formats, interfaces, libraries, services

• **Data curators:** preserve data content and integrity of science data and metadata in archives

• **Research funding agencies, professional societies, governments:** encourage free and open access to research data, advocate elimination of most access restrictions
Growth in data from sensor systems

According to Science article [2011-02-11, Baraniuk]:

- Majority of data generated each year now comes from sensor systems
- Amount generated passed storage capacity in 2007
  - in 2010 the world generated 1250 billion gigabytes of data
  - generated data growing at 58% per year
  - storage capacity growing at 40% per year
- We generate more scientific sensor data than we can process, communicate, or store (e.g. LHC)
Data challenges: gigabytes to exabytes

Scalability and “Big Data”

- What’s the big deal about big data?
  - aren’t more and faster computers and larger disks the solution?
- I/O access and bandwidth can’t keeping up with computing speed
- Too big to transfer, must move processing to data
- Sensors and models can generate huge datasets easily
- Making huge datasets accessible and useful is difficult
- Other problems: discovery, curation, provenance, organization, integrity, ...
Infrastructure for sharing scientific data

- Applications depend on lower layers
- Sharing requires agreements
  - formats
  - protocols
  - conventions
- Data needs metadata
- Is all this infrastructure really necessary?
Why not use binary I/O?

Simple, but ...

• Not portable
• Lacks metadata for use, discovery
• Not usable by general analysis and visualization tools
• Inaccessible from other programming languages, for example reading Fortran binary data from Java or C/C++
Why not use formatted I/O?

```
real :: a(len), b(len)

write (nunit, '(10f10.3') a
read  (nunit, '(10f10.3') b
```

Simple, but ...

- Inefficient for large datasets (time and space)
- Sequential, not direct ("random") access
- Lacks metadata for use, discovery
- Not usable by general analysis and visualization tools
Why not use relational databases?

- Data model may not be appropriate
  - no direct support for multidimensional arrays
  - tables and tuples are wrong abstractions for model output, coordinate systems
- Tools: lacking for analysis and visualization
- Portability: difficult to share, publish, preserve, cite, database contents
- Performance
  - database row orientation slows access by columns
  - transactions unnecessary for most scientific use
- But sometimes databases are ideal, e.g. virtual observatories
Other alternatives for scientific data

• XML, YAML, JSON, CSV, other text notations
  – Require parsing
  – Sequential, not direct access
  – Inefficient for huge datasets
  – Conversions between text and binary can lose precision

• Discipline-specific: FITS (astronomy), GRIB (meteorology), XMDF (hydrology, meshes), fooML, ...

• General-purpose, for scientific data:
  – CDF: historically one of the first, used in NASA projects
  – netCDF: widely used, simplest data model
  – HDF5: most powerful, most complex data model
  – SciDB: coming soon, multidimensional array-based database
An example: model outputs for IPCC AR5
What is the IPCC?

The Intergovernmental Panel on Climate Change

- 1990 - First Assessment Report
- 1995 - Second Assessment Report
- 2001 - Third Assessment Report
- 2007 - Fourth Assessment Report
- 2013 - Fifth Assessment Report
What was the IPCC AR4?

“The 4th Assessment Report of the Intergovernmental Panel on Climate Change”

Working Group I Report: "The Physical Science Basis"

Working Group II Report: "Impacts, Adaptation and Vulnerability"

Working Group III Report: "Mitigation of Climate Change"
What was the IPCC AR4?

The first large-scale coordination of climate modeling efforts, data analysis, data management and data dissemination by the global climate modeling community: 24 global coupled climate models from 16 modeling centers located around the world.

<table>
<thead>
<tr>

</tbody>
</table>
What is the IPCC AR5?

“The 5th Assessment Report of the Intergovernmental Panel on Climate Change”

The second large-scale coordination of climate modeling efforts, data analysis, data management and data dissemination by the global climate modeling community: 20+ global coupled climate models from 15+ modeling centers located around the world

Many more experiments than AR4:

- Decadal Prediction Experiments
- Long Term Experiments

Publishing scientific data: advice to data providers
Advice about unsolicited advice

• I could just present advice I think is needed
• I would rather listen, find out what is needed from data management infrastructure
• Consider the following the start of a dialogue
Don’t just provide pictures, provide data

http://www.some-archive.org/id3456/my-results/

• So your research can be reused by others in future research and analyses
• So your plots can be duplicated and integrated with other data
• So users can choose their favorite display and analysis software for your data
• So corrections to data are practical
• So your results have a longer shelf life
Don’t just make data available interactively

- Programs need access to data, not just humans
- Accessing lots of data by mouse clicks or display touching is difficult and slow
- Provide bulk access for large datasets
- Anticipate need for programs to access data remotely
Support efficient access to small subsets of data

- Database queries should return only requested data
- Don’t provide only huge files with all the data, that discourages reuse
- Remote access is faster for small subsets
- Interactive visualization integrating data from multiple sources is practical with small subsets
- Some problems require a little data from many places, not a lot of data from one place
Provide easy access to metadata

• More metadata is usually better
• Make it easy to add more metadata later
• Keep metadata with the data, if practical
• Support *discovery metadata*, so your data can be found
  – coordinate systems
  – units
Strive for interoperability

- Data should be portable now
- Data should be portable to the future
- Don’t optimize packaging or format for specific data or application
- Valuable scientific data is written once, read many times
Support standards

• If available, use them
• If not, help develop them
• If possible, help maintain them
Summary: What Data Producers Should Provide

- Data (not just visualizations)
- Useful metadata (not just data)
- Remote access (not just physical copies or local access)
- Convenient granularities of access (not too large or too small)
- Program access (not just for interactive users)
- Standard formats (not machine-, application-, or language-specific; but what about discipline-specific?)
- Organization for users and readers (not just what’s most convenient for provider)
But scientists want to do science ...

- ... not data management
- Valuable scientific data must be acquired, organized, accessed, visualized, distributed, published, and archived
- How can scientists do all this and still have time to do science?
  - graduate students?
  - data managers, curators, stewards, ...?
  - database systems?
  - general purpose scientific data infrastructure?
- Standards supported by open source software may help:
Questions / Discussion
